Lecture 08 Analog Input

CE346 – Microprocessor System Design Branden Ghena – Fall 2023

Some slides borrowed from: Josiah Hester (Northwestern), Prabal Dutta (UC Berkeley)

Administrivia

- Project proposals are due tonight!
 - Plan is to get you project proposal feedback over the next several days
 - 18 out of 60 students submitted already (7 groups)

- Remember to answer the post-lab questions on Canvas!
 - You can do them late if you forget, but don't forget

Today's Goals

- Explore methods for sensing analog signals
 - Comparators
 - Analog-to-Digital Converters
- Discuss nRF implementation of these peripherals

Outline

Comparators (and nRF implementations)

General ADC Design

nRF ADC Implementation

Analog signals

- Exist in infinite states
 - From a maximum to a minimum
- Often used for interactions with the real world
 - Sensors usually generate analog signals
- Microbit example: microphone

Interacting with analog signals

Microcontrollers are inherently digital

Need a method for translating analog signal into a digital one

Options:

- 1. Determine if signal is higher or lower than some amount (Boolean)
- 2. Determine voltage value of signal (N-bit number)

Determination is done by a Comparator

General comparator design

 Compares an analog input signal to a reference voltage

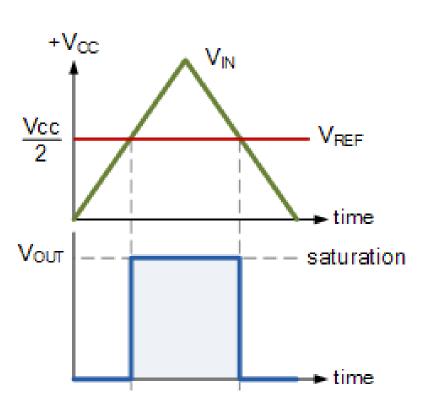

V_{OUT} digital signal

• High: $V_{IN} > V_{REF}$

• Low: $V_{IN} < V_{REF}$

- Advantages:
 - Simple
 - Low power

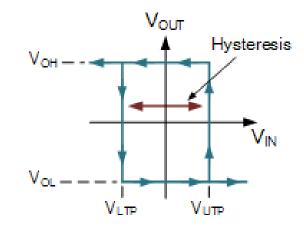

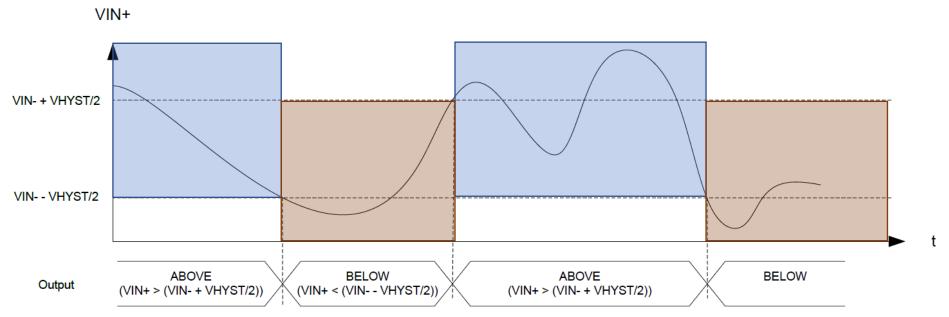

Comparator design questions

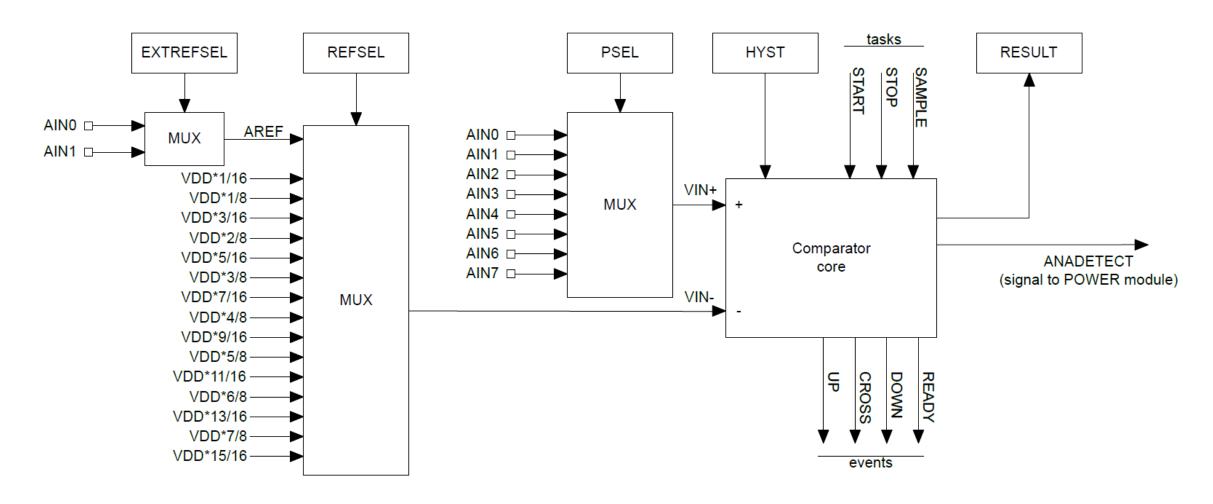

- What reference voltages are available?
 - A few internal voltages
 - Usually also allows external references from input pins
- When is an output generated?
 - Usually when status changes
 - Low-to-high, High-to-low, Both (like GPIO interrupts)

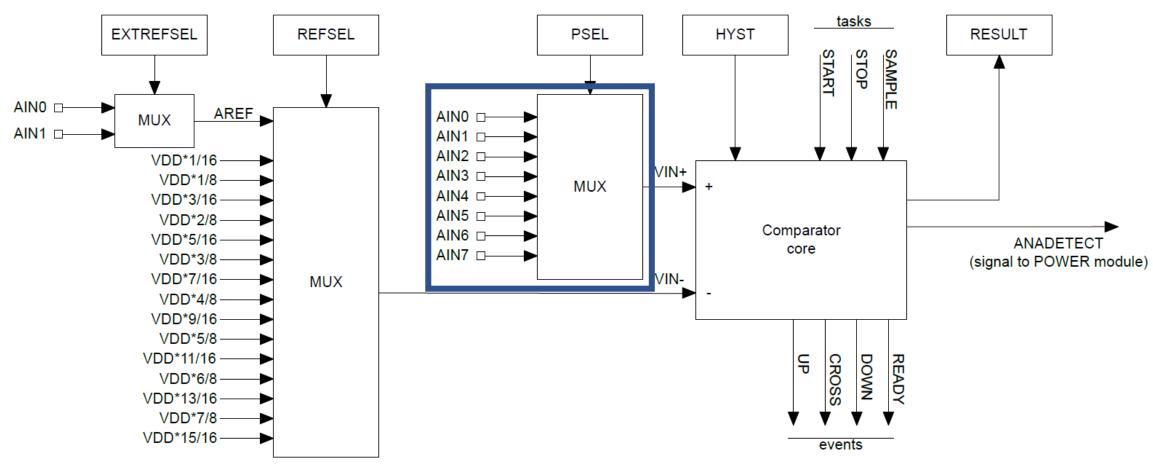

Hysteresis

 A window added around signal state changes to prevent small amounts of noise from changing the output

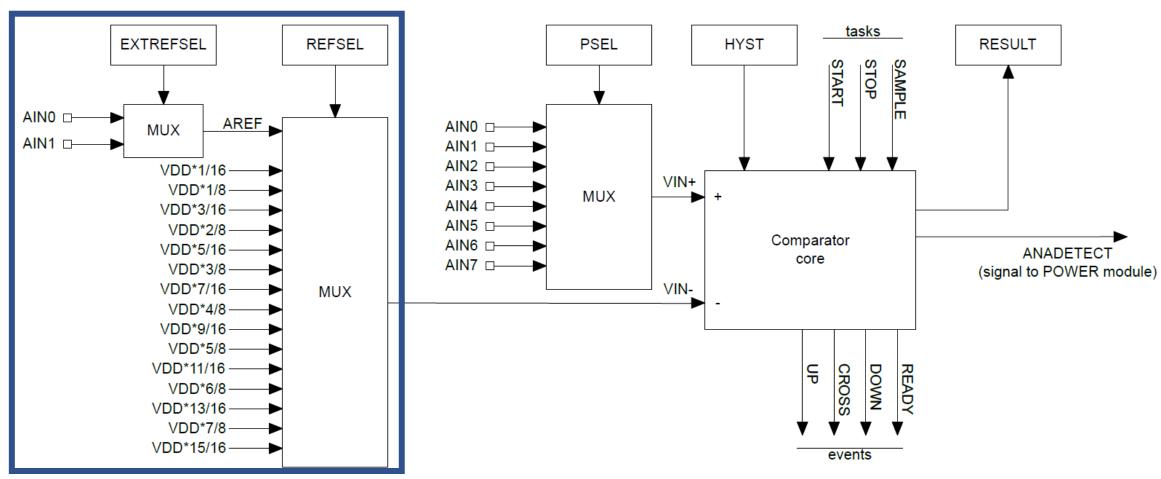

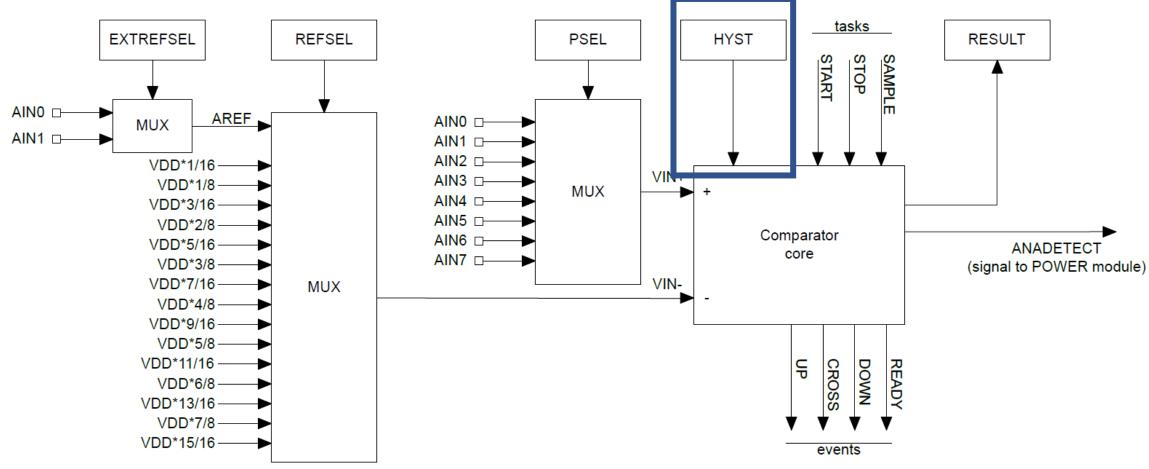

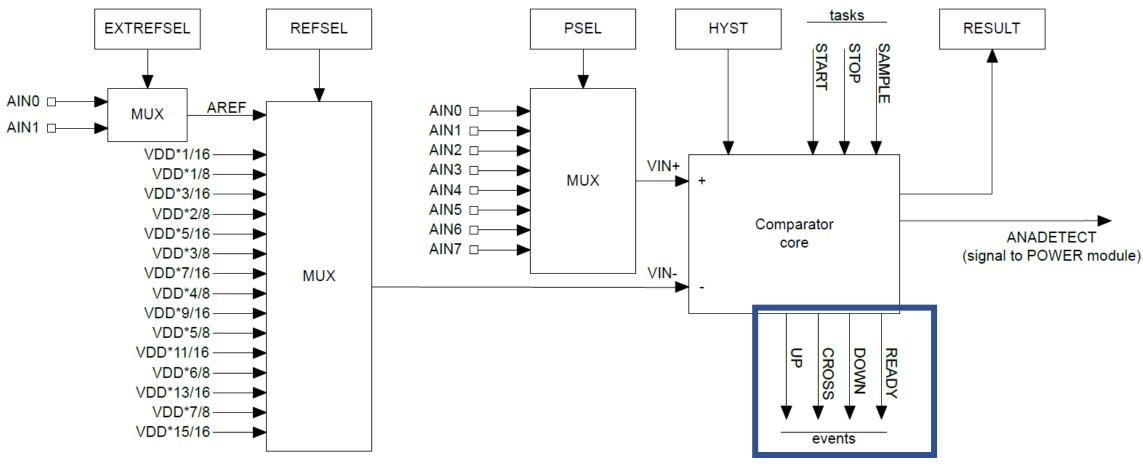

Input: one of eight analog input pins

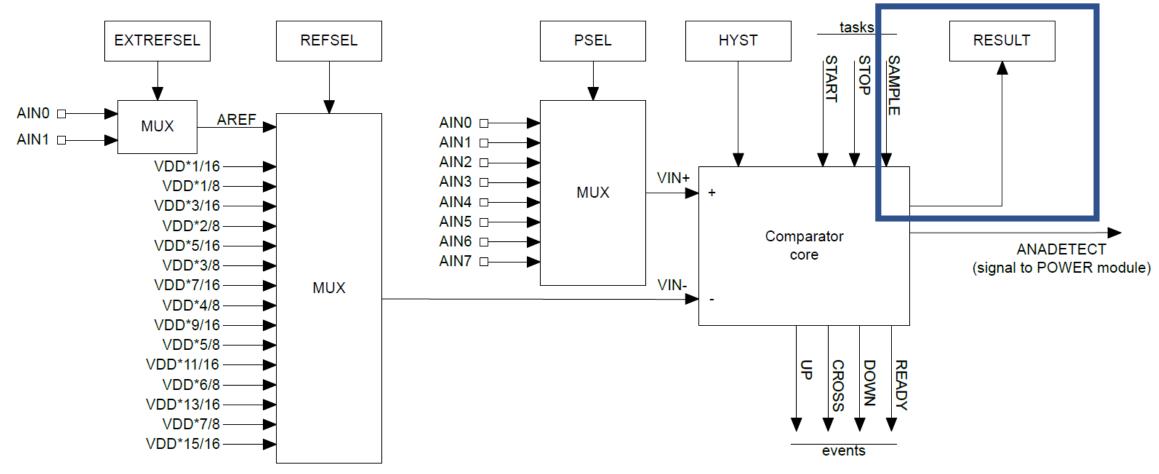

- Reference: one of two analog inputs or selection of VDD * N/16
 - VDD: Input voltage of the system

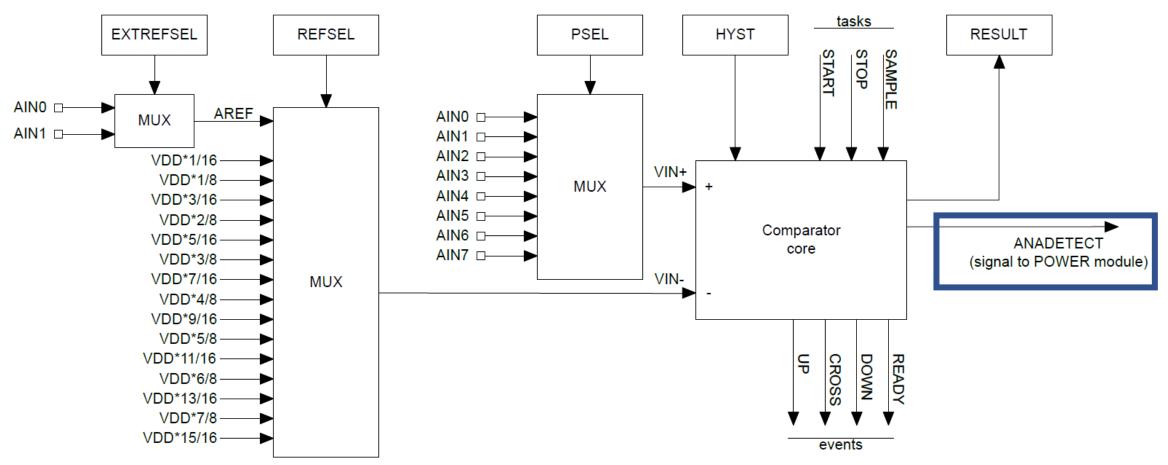

• Hysteresis: +/- 50 mV range around VIN- when enabled

• Events: transition signals + ready (~150 µs startup time)

Can also request what the current comparison state is (high/low)

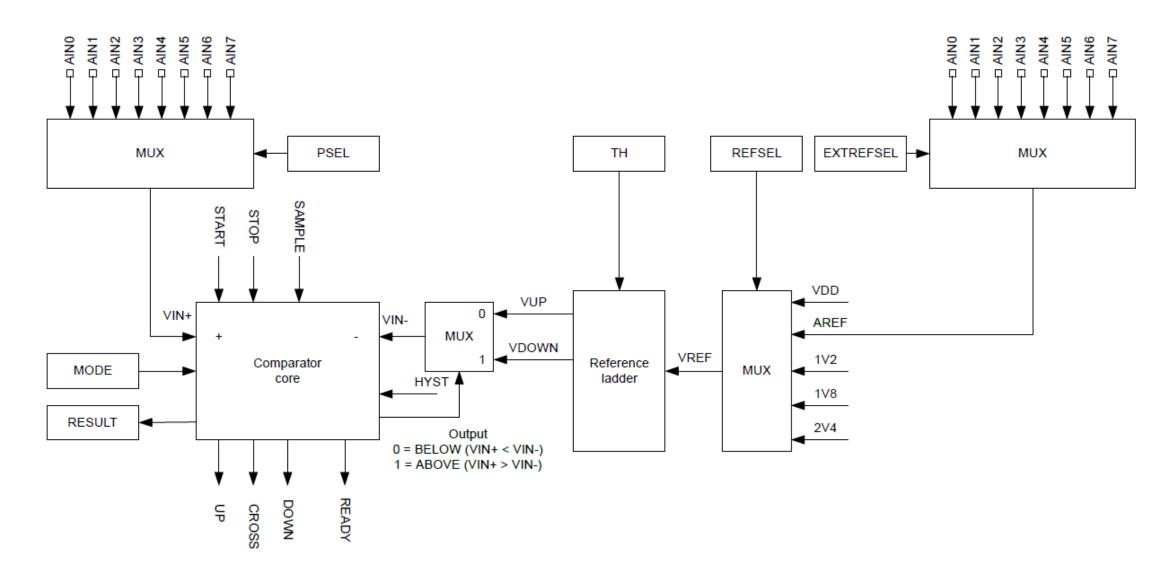

• Can be used for low-power wakeup of microcontroller

nRF COMP peripheral

- Analog Comparator (not low power)
 - More advanced version of a comparator (otherwise similar)
- What advantages would a more capable comparator have?
 - Configurable hysteresis
 - LPCOMP: +/- 50 mV COMP: any of the N/64 voltage levels
 - Faster detection
 - LPCOMP: 5 μs COMP: 0.1-0.6 μs (depending on power mode)
 - More possible reference voltages
 - LPCOMP: VDD or input COMP: VDD, 1.2v, 1.8v, 2.4v, or input
 - LPCOMP: 16 levels COMP: 64 levels

nRF COMP peripheral

Break + Question: Internal reference voltages

Why have internal voltage references other than VDD?

Break + Question: Internal reference voltages

Why have internal voltage references other than VDD?

- What if want you want to measure is VDD?
 - Battery voltage
 - Did someone just unplug me?
 - etc.
- What if VDD isn't stable?
 - Battery voltage
 - Energy-harvesting system
 - Hard to know what any particular value means...

Interacting with analog signals

Microcontrollers are inherently digital

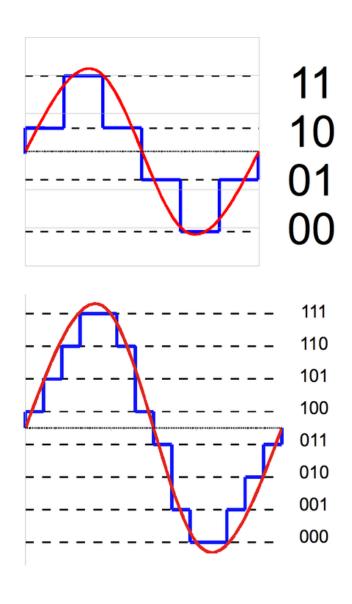

Need a method for translating analog signal into a digital one

Options:

- 1. Determine if signal is higher or lower than some amount (Boolean)
- 2. Determine voltage value of signal (N-bit number)

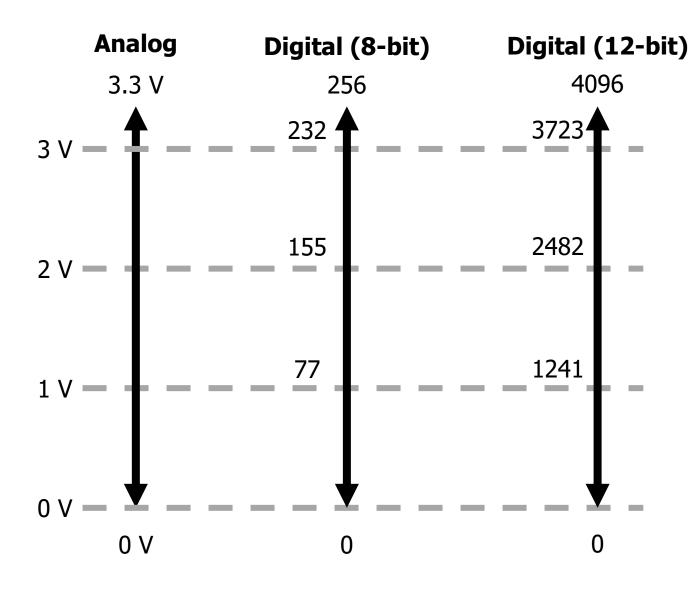

Translation is done by an Analog-to-Digital Converter (ADC)

Quantization

- Analog voltages are represented by discrete voltage levels
- Comparators are 1-bit ADCs
 - Split into two regions
 - Good ADCs split into 4000-16000 regions
- More levels gives a more accurate representation of the signal

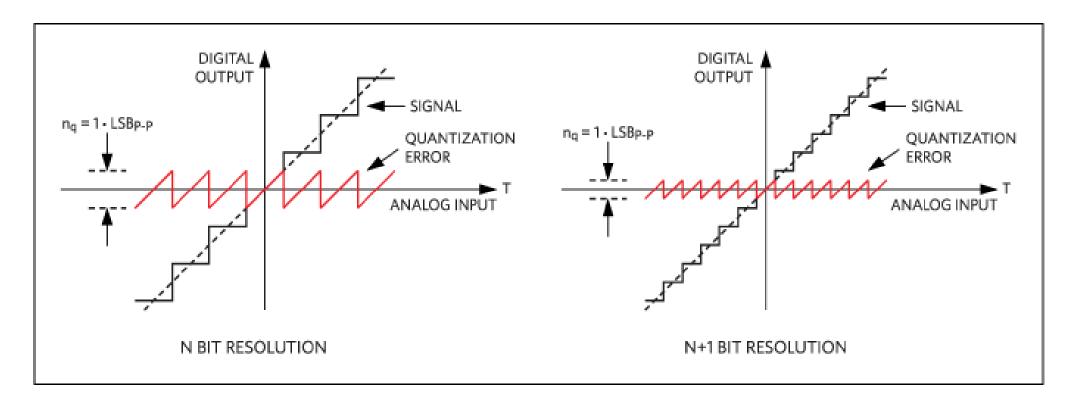

Translating voltage and ADC counts

$$Value = \frac{V_{IN}}{V_{REF}} * (2^{Resolution})$$

- V_{REF} selects maximum range
- Ground is usually minimum range
- Resolution depends on hardware
 - Either hardcoded or a selection

Quantization error

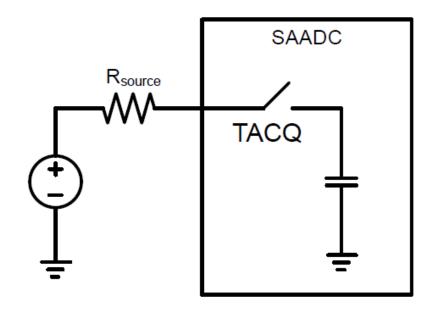

- Resolution choice determines magnitude of error
 - Each extra bit halves the magnitude of error

Analog to digital translation process

Two steps:

1. Acquisition

- Read in signal for some amount of time
- Signal connected to a capacitor
- Fills capacitor up to voltage level
- Speed depends on input resistance
 - 1-100 µs is common

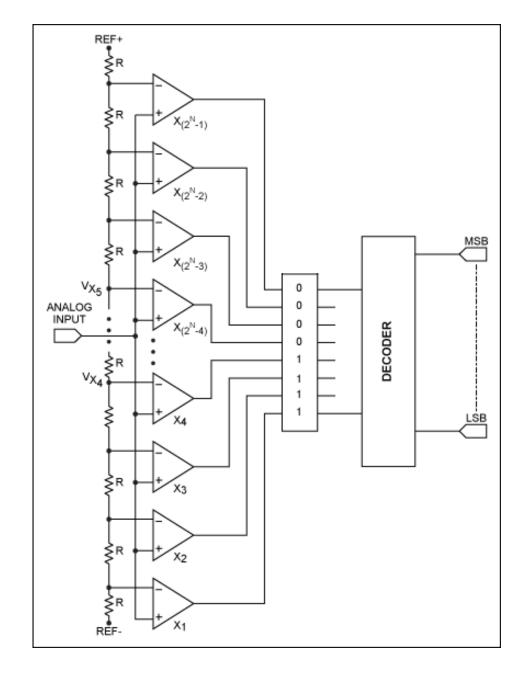

2. Conversion

Determine which digital value the read signal corresponds to

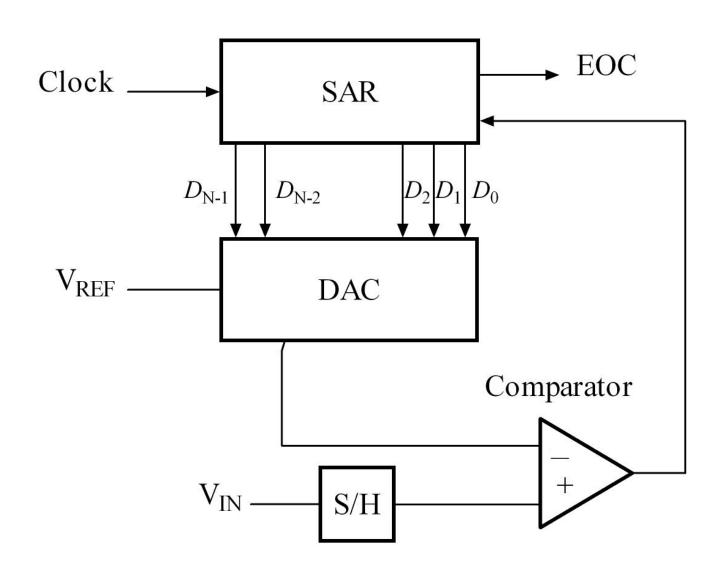

Direct-conversion ADC

- Chain comparators together
 - Each with a separate reference voltage
- Digital value determined immediately
 - Also known as "Flash" ADCs
- Downside: needs 2ⁿ-1 comparators
 - Reserved for expensive applications

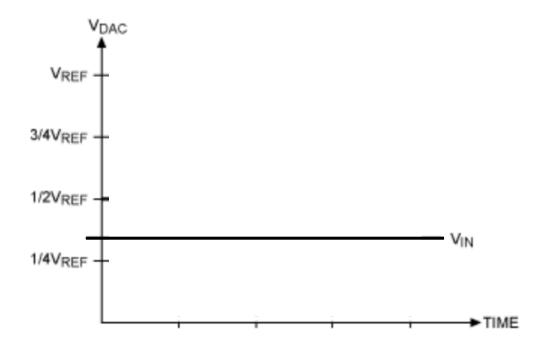

Successive-Approximation ADC

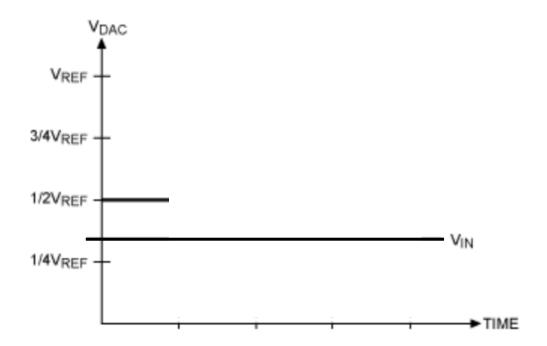

- Method: Binary Search
 - Compare signal to generated reference
 - Increase or decrease reference as needed
 - Repeat
- DAC creates reference (Digital-to-Analog Converter)
 - Final value of DAC is the ADC value

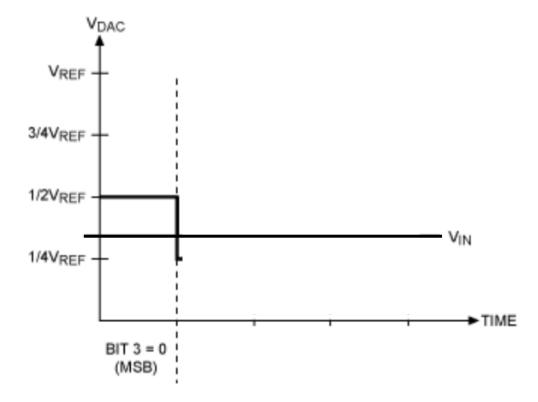

4-bit ADC with an input signal V_{IN}

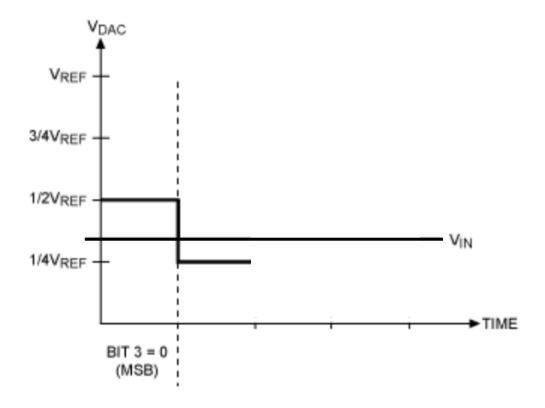

- 1. Compare $\frac{1}{2}$ V_{REF} (0b????) to V_{IN}
 - If V_{IN} is greater, bit is 1. Else zero

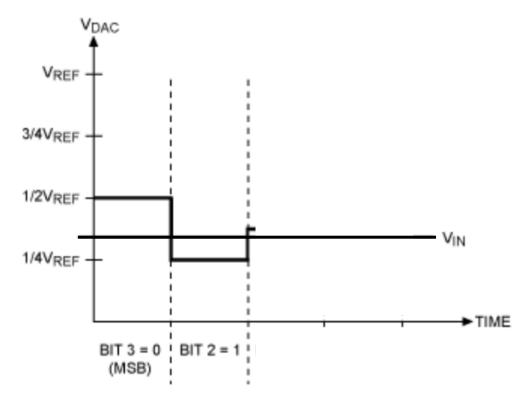

- 1. Compare $\frac{1}{2}$ V_{REF} (0b**0**???) to V_{IN}
 - If V_{IN} is greater, bit is 1. Else zero
 - V_{IN} is less. So set that bit to zero

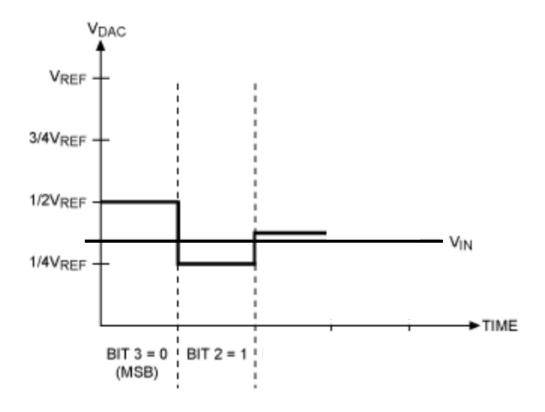

- 2. Compare 1/4 V_{REF} (0b**0**???) to V_{IN}
 - If V_{IN} is greater, bit is 1. Else zero

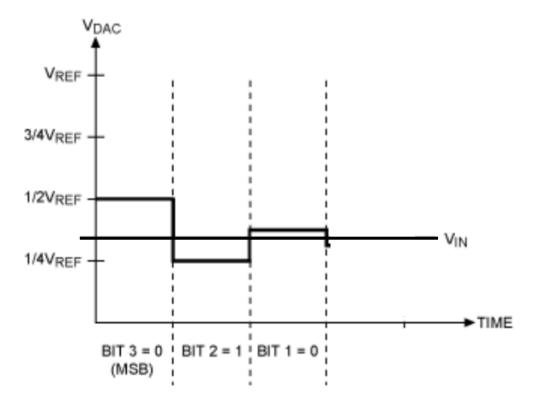

- 2. Compare $1/4 V_{REF} (0b$ **01** $??) to <math>V_{IN}$
 - If V_{IN} is greater, bit is 1. Else zero
 - V_{IN} is greater. So set that bit to one

- 3. Compare $3/8 V_{REF} (0b$ **01** $??) to <math>V_{IN}$
 - If V_{IN} is greater, bit is 1. Else zero

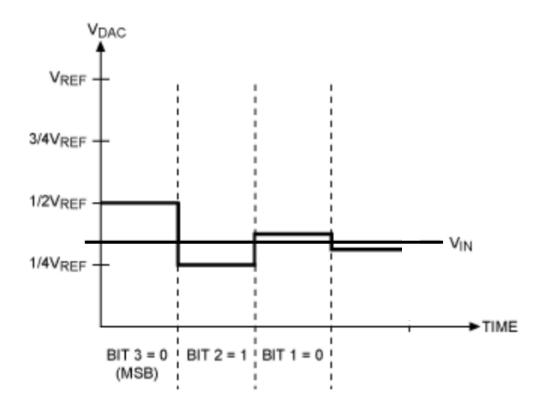

- 3. Compare $3/8 V_{REF}$ (0b**010**?) to V_{IN}
 - If V_{IN} is greater, bit is 1. Else zero
 - V_{IN} is less. So set that bit to zero

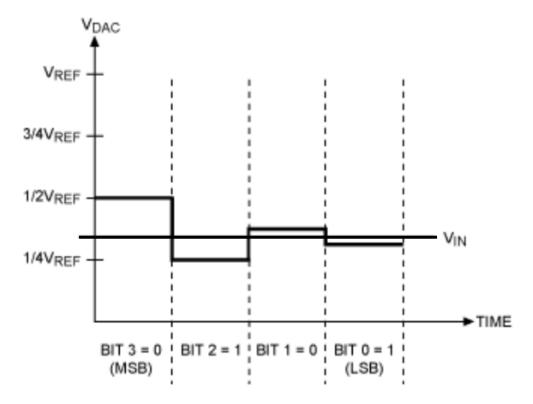

Successive Approximation Example

- 4. Compare 5/16 V_{REF} (0b**010**?) to V_{IN}
 - If V_{IN} is greater, bit is 1. Else zero

Successive Approximation Example

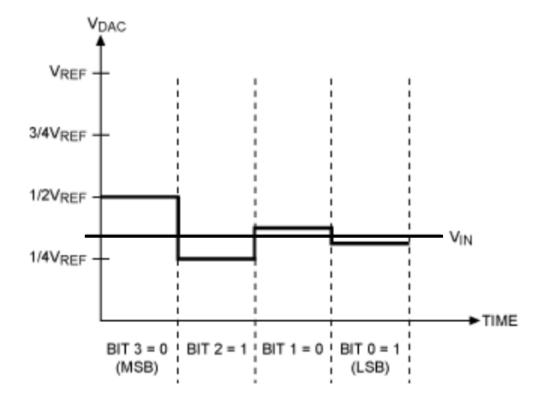

- 4. Compare $5/16 V_{REF} (0b$ **0101** $) to <math>V_{IN}$
 - If V_{IN} is greater, bit is 1. Else zero
 - V_{IN} is greater. So bit is one

Successive Approximation Example

5. Output is $5/16 V_{REF}$ (0b0101)

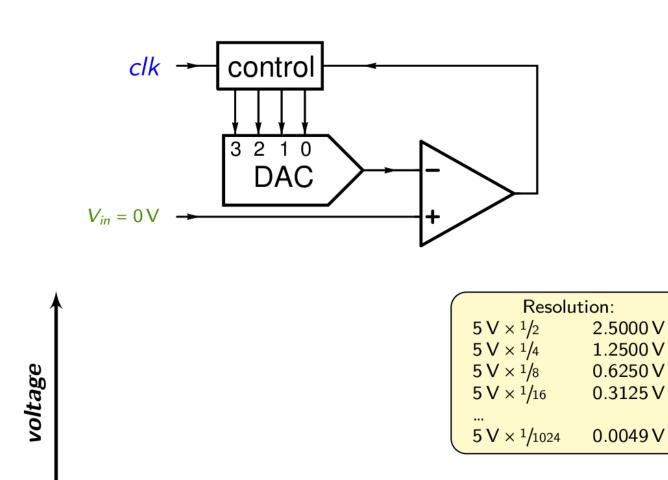

- Slight underestimate of the real value, but as close as we can get
- More bits would get us even closer

Successive Approximation – example of a 4-bit ADC

Successive Approximation Example

 Performs a binary search to determine correct reference signal value

time

 $V_{in} = 0 \text{ V}$

Tradeoffs in ADC design

- Direct-Conversion: more expensive (more silicon)
- SAADC: more time consuming (more binary search time)

- Most microcontrollers land on successive-approximation designs
 - The slowdown isn't an issue for slowly changing signals
 - Quickly changing signals probably need special hardware anyways

Break + Critical Thinking

How much ADC resolution is needed?

Break + Critical Thinking

How much ADC resolution is needed?

- Resolution requirement depends on signal being sensed
- Temperature sensor probably doesn't need 16-bit ADC
 - Difference between 30.001°C and 30.002°C is usually irrelevant

- Microphone might though!
 - Differences are audible until they are small enough
 - 16-bit or 24-bit tend to be common choices for audio data

nRF ADC Implementation

nRF SAADC (Successive Approximation ADC)

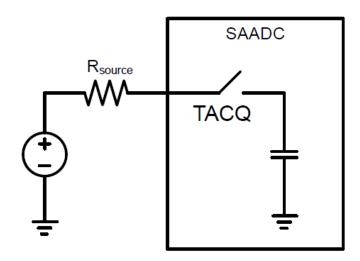

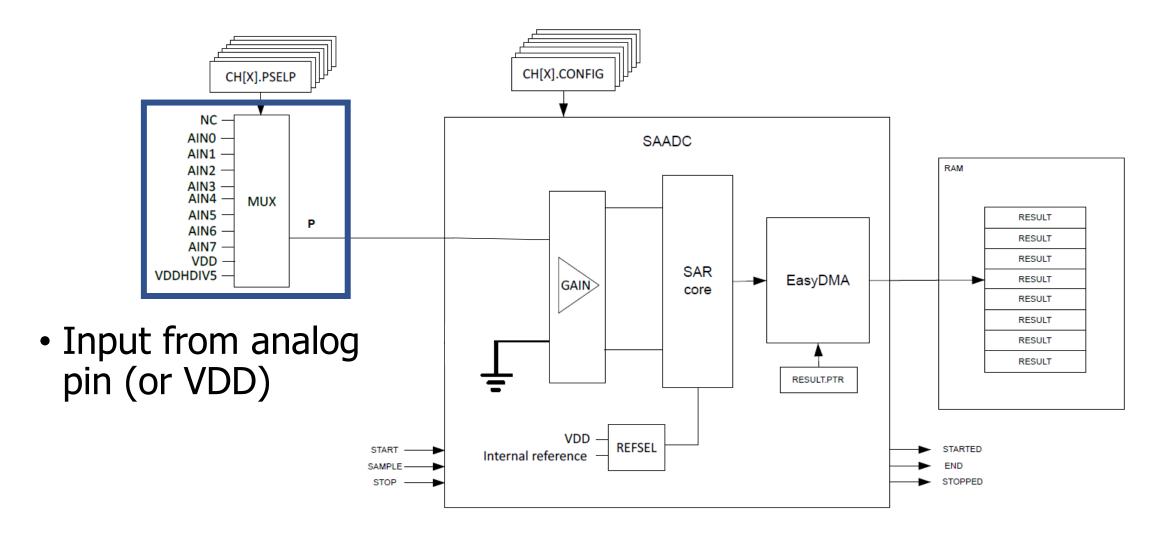

Essentially virtualization in hardware!

SAADC Resolution and Sampling

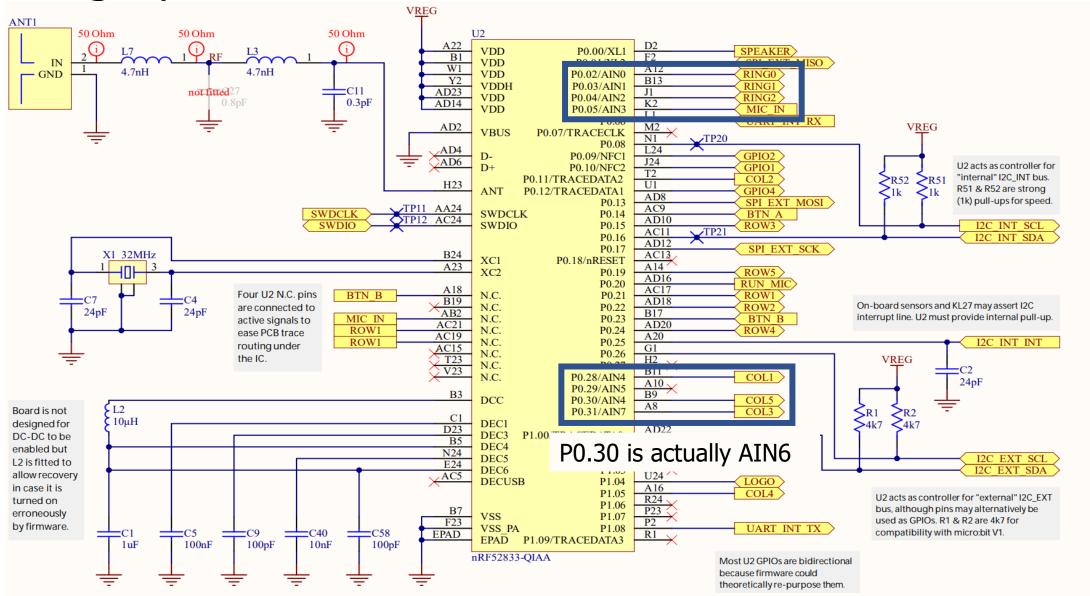

- Resolution is selectable (for the whole peripheral)
 - 8, 10, 12, or 14 bits
 - Result stored as 16-bit value regardless

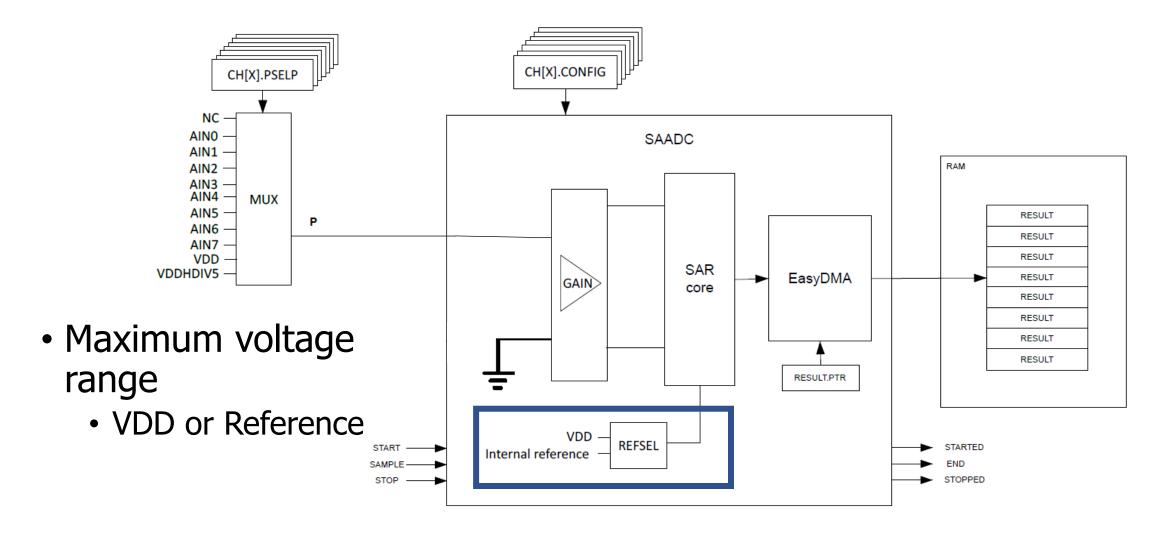

- Sampling time is selectable (for each channel)
 - 3-40 µs
 - Longer sampling time is important for very low-current signals

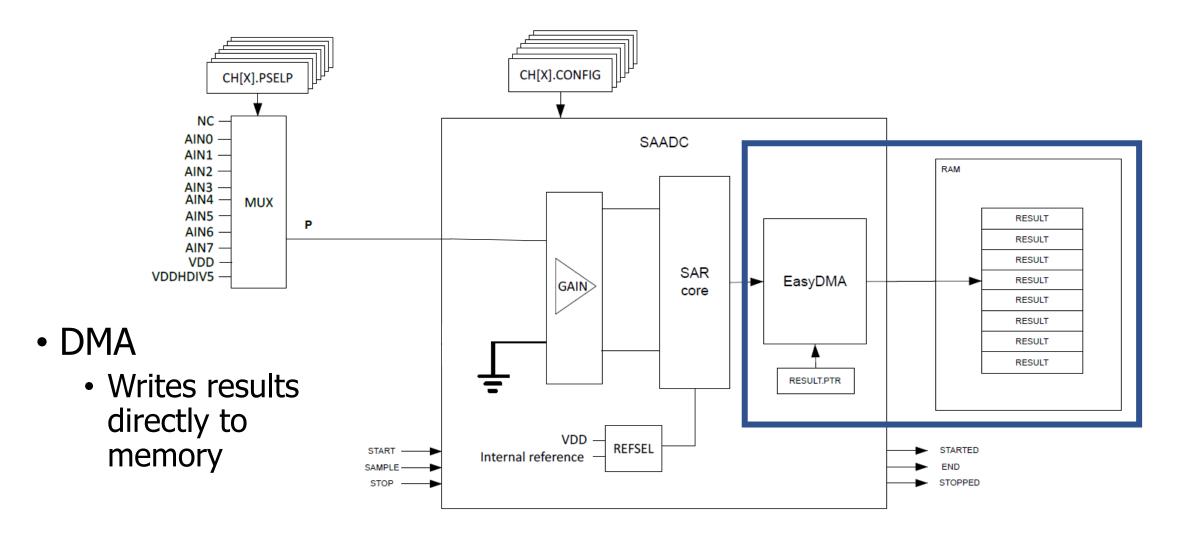

Analog inputs on the Microbit

Triggering sample collection

- Can be triggered with TASK_START on demand
 - Including through EVENT->TASK chaining

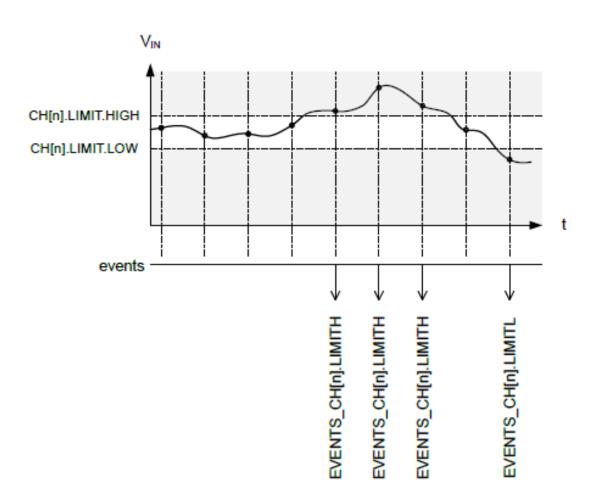

- Includes a timer within itself to automatically trigger sampling
 - Rate = $16 \text{ MHz} / (2^{\text{Scale}})$ where scale is 11 bits
 - Maximum rate is 7.8 kHz

EasyDMA on the SAADC

- There is no register to read ADC results from
- Instead, you must use DMA to collect samples
- At configuration time, provide:
 - Pointer to RAM
 - Must be RAM, not Flash
 - Maximum count of 16-bit samples to be written starting at address
 - Up to 32768
- When complete, a register tells you the amount of samples written to RAM

Event limit monitoring

- Includes two comparators for each channel
 - High and Low limits
- Generates events whenever transitioning to above High or below Low
 - Events can be ignored if unnecessary

Temperature sensitivity

- ADCs are often temperature sensitive
 - nRF SAADC: 0.02% per degree C
- Recommends recalibrating every change of 10 degrees C or more
 - Automatic task for calibration
 - Real concern for deployed devices
 - Outdoors
 - Wearable

Design question

How many analog samples can the Microbit hold?

Design question

- How many analog samples can the Microbit hold?
 - Available: 128 kB RAM, 512 kB Flash (64000 samples in RAM)
 - Questions
 - Are they packed or padded to 16-bit?
 - How much memory are you using for other things?
 - Are you moving them into Flash periodically? (or external storage)
